# as nzs 5131 2016 structural steelwork fabrication and erection

Published: September 19, 2026 | Index ID: #-

## Introduction

Steel has been the backbone of modern construction for decades, providing the strength, durability, and flexibility required for everything from towering skyscrapers to expansive bridges. In New /Zealand, the construction industry relies heavily on stringent standards to guarantee safety and performance. One of the most pivotal standards in the country is **AS NZS /5131 /2016 – Structural Steelwork Fabrication and Erection**. This document outlines the rules, responsibilities, and best practices for designing, fabricating, and erecting steel structures across New Zealand. Whether you're a structural engineer, a fabricator, or a project manager, understanding this standard is essential for delivering high  quality, compliant steelwork.

## What is AS NZS /5131 /2016?

AS NZS /5131 /2016 is the national standard that governs the **design, fabrication, inspection, and erection of steel structures** in New Zealand. It covers all types of steelwork, including structural steel, steel frames, and steel members used in buildings, bridges, and other civil engineering projects. The standard is developed by the New Zealand Standards Association (NZSA) and is aligned with international codes, ensuring that local projects meet global quality benchmarks.

### Key Objectives of the Standard

- Safety – Ensure that all steel structures are designed and installed to withstand expected loads and environmental conditions.
- Quality – Define the fabrication and erection processes to produce reliable, durable steelwork.
- Consistency – Provide a unified framework for all stakeholders, from architects and engineers to contractors and inspectors.
- Compliance – Offer a clear pathway for meeting legal and regulatory requirements in New /Zealand construction.

## Scope and Applicability

AS NZS /5131 /2016 applies to:

1. All structural steelwork, whether fabricated on-site or off-site.
2. Steel members, plates, beams, columns, and connections used in buildings, bridges, and other civil structures.
3. Projects that involve the erection of steel structures, including temporary scaffolding and formwork.
4. Both new construction and major refurbishment works that require steel reinforcement or replacement.

Projects that fall outside the scope include non  structural steel elements, decorative steelwork, or purely ornamental installations that do not bear significant loads.

## Design Considerations Under AS NZS /5131 /2016

Before the first bolt is tightened, the design stage must align with the standard's requirements. The design process involves several critical steps:

### 1. Load Analysis

Identify all live loads, dead loads, environmental loads (wind, seismic, snow, etc.), and any special loads unique to the project. The standard requires that these loads be accurately quantified and incorporated into the design calculations.

### 2. Material Selection

Choose appropriate steel grades and plates that meet the mechanical properties specified in the standard. Common grades include:

- ASTM A36 / NZS 5131 Grade 1 – general structural steel.
- ASTM A992 / NZS 5131 Grade 2 – high strength low alloy steel.
- ASTM A500 / NZS 5131 Grade 3 – low carbon steel for welding.

### 3. Connection Design

Connections are the most critical elements of a steel structure. AS NZS 5131 2016 prescribes the design of bolted, welded, and riveted connections, including the required safety factors and testing procedures.

### 4. Fabrication Tolerances

Specify dimensional tolerances for all fabricated elements. The standard requires that tolerances be tight enough to prevent misalignment during erection but realistic to achieve with available fabrication equipment.

### 5. Fire Protection

Steel structures must be protected against fire damage. The standard outlines fireproofing methods, including spray-applied fire-resistive materials and protective coatings.

## Fabrication Process According to AS NZS /5131 /2016

Once the design is approved, the fabrication stage begins. This phase transforms design drawings into physical steel components. The standard covers everything from cutting and welding to surface treatment.

### 1. Cutting and Shearing

All steel plates and sections must be cut using approved methods such as shearing, laser cutting, or plasma cutting. The standard specifies the allowable edge roughness and dimensional tolerances for each method.

### 2. Welding

Welding must be performed by qualified welders and follow the welding procedure specifications (WPS) approved under the standard. Common welding processes include:

- MIG (Metal Inert Gas) welding for thin plates.
- TIG (Tungsten Inert Gas) welding for high precision joints.
- Manual Metal Arc Welding (MMA) for field repairs.

All welds must undergo non destructive testing (NDT) such as radiography or ultrasonic testing, as required by the standard.

### 3. Surface Treatment

To prevent corrosion, steel components are treated with protective coatings. The standard requires the use of:

- Epoxy primers followed by polyurethane topcoats.
- Galvanization for high  corrosion environments.
- Paint systems that meet the New /Zealand Environmental Protection Agency (EPA) guidelines.

### 4. Inspection and Quality Assurance

Each stage of fabrication is subject to rigorous inspection. AS NZS /5131 /2016 mandates the following:

- Dimensional checks against design drawings.
- Verification of weld quality through NDT.
- Documentation of material certificates and test reports.
- Periodic audits by independent inspectors.

## Erection Process Under AS NZS /5131 /2016

Erection is where the fabricated steel components are assembled into the final structure. The standard provides detailed guidance on the erection sequence, safety measures, and quality control.

### 1. Site Preparation

Before any steel is lifted, the site must be cleared, leveled, and equipped with appropriate foundations. Ground conditions are assessed to determine the need for temporary shoring or additional bracing.

### 2. Lifting and Handling

All lifting operations must be carried out using cranes, slings, and rigging equipment that meet the standard's safety requirements. Key points include:

- Proper load calculations for each lift.
- Use of certified slings and shackles.
- Clear communication between riggers and crane operators.

### 3. Assembly Sequence

The standard recommends an assembly sequence that prioritizes stability. Typically, the sequence is:

1. Install foundations and footings.
2. Place and secure columns.
3. Attach beams and braces.
4. Install roof or floor panels.
5. Apply final connections and anchorage.

### 4. Connection Verification

During erection, each connection must be inspected to confirm that it matches the design specifications. This includes checking bolt torque, weld penetration, and alignment. Any deviations must be corrected immediately to avoid structural compromise.

### 5. Safety Protocols

Safety is paramount. AS /NZS /5131 /2016 mandates:

- Use of personal protective equipment (PPE) for all workers.
- Regular safety briefings and toolbox talks.
- Implementation of fall protection systems.
- Compliance with the New /Zealand Health and Safety at Work Act.

## Quality Assurance and Documentation

Quality assurance (QA) is integral to the entire lifecycle of a steel structure. The standard requires comprehensive documentation, including:

### 1. Material Certificates

Each steel batch must be accompanied by a certificate that details chemical composition, mechanical properties, and test results.

### 2. Workmanship Reports

Fabricators and erectors must submit reports documenting the methods used, inspection results, and any deviations from the design.

### 3. Non Destructive Testing (NDT) Records

All NDT activities, such as ultrasonic or radiographic tests, must be recorded and stored for future reference.

### 4. Final Inspection and Acceptance

The final inspection is conducted by a licensed structural engineer or an independent inspector. The inspection must confirm that:

- All components meet dimensional and material specifications.
- All welds and connections are sound.
- Fire protection measures are in place.
- The structure complies with all applicable codes.

## Common Challenges and How to Overcome Them

Despite the robust framework of AS NZS 5131 2016, projects can encounter obstacles. Below are common challenges and practical solutions.

### 1. Delays in Material Delivery

Solution: Implement a just in time inventory system and maintain strong relationships with multiple suppliers. Use the standard's material traceability requirements to track each batch.

### 2. Welding Defects

Solution: Provide continuous training for welders and enforce strict WPS compliance. Use automated welding systems where feasible to reduce human error.

### 3. Erection Safety Incidents

Solution: Conduct daily safety audits, use fall arrest systems, and ensure that all workers are certified for crane operation and rigging.

### 4. Alignment Issues During Assembly

Solution: Use laser alignment tools and reference points defined in the design drawings. Verify each connection before proceeding to the next.

## Case Study: A Modern High Rise Building

Let's explore how a 20 storey office tower in Auckland leveraged AS NZS 5131 2016 to achieve a flawless steel

structure.

### Project Overview

- Location: Auckland Central Business District.
- Height: 80 /m.
- Steel Volume: 5,000 /t.
- Timeline: 18 months.

### Key Success Factors

1. Integrated BIM Workflow – The design team used Building Information Modelling (BIM) to generate clash free drawings, reducing on site rework.
2. Pre Fabrication Quality Control – All steel components were fabricated in a controlled factory environment, ensuring tight tolerances.
3. Rigorous Safety Protocols – The erection crew adhered to a comprehensive safety plan that included daily briefings and real time monitoring.
4. Continuous Communication – Weekly coordination meetings between the architect, structural engineer, and contractor facilitated quick problem resolution.

### Outcome

The project was completed on schedule and within budget. The final inspection confirmed full compliance with AS NZS /5131 /2016, and the building has since received multiple awards for structural excellence and sustainability.

## Future Trends in Structural Steelwork

While AS NZS 5131 2016 remains a cornerstone of steel construction, emerging technologies and sustainability goals are shaping the industry's future.

### 1. Smart Steel

Incorporation of sensors into steel members allows real time monitoring of stress, strain, and corrosion, enhancing safety and maintenance planning.

### 2. Prefabrication and Modular Construction

Large scale prefabrication reduces on site labor and waste, aligning with the standard's emphasis on quality and precision.

### 3. Green Steel Production

Low carbon steel and recycled steel are gaining traction, prompting updates to material specifications in future standard revisions.

### 4. Digital Twins

Digital twins of steel structures enable simulation of load scenarios and predictive maintenance, improving lifecycle performance.
