2. Fundamental Concepts – Thermodynamics, material balances, and unit operations.
3. Modeling Workflow – From data entry to simulation execution.
4. Unit Operations – Detailed instructions for each equipment type.
5. Thermodynamic Models – Selection criteria and implementation.
6. Advanced Topics – Dynamic simulation, optimization, and scripting.
7. Case Studies – Practical examples for refineries, petrochemicals, and specialty chemicals.
8. Appendices – Glossary, references, and troubleshooting tips.

4. Building Your First Simulation

4.1 Defining the Problem

Before you open HYSYS, clearly articulate what you want to achieve. Typical objectives include:

- Determine the optimum operating pressure for a distillation column.
- Estimate the yield of a catalytic cracking unit.
- Assess the impact of a new feedstock on existing processes.
- Quantify the energy savings from a heat integration strategy.

4.2 Gathering Input Data

Accurate simulations rely on reliable data:

- Feed composition (molar or mass fractions).
- Temperature and pressure conditions.
- Equipment specifications (e.g., column internals, heat exchanger geometry).
- Process constraints (e.g., safety limits, environmental regulations).
- Historical performance data (if available).

4.3 Setting Up the Model

1. Create a New Project – Choose a project name and directory.
2. Define the Feed – Input the composition, flow rate, temperature, and pressure.
3. Select a Property Method – Pick the thermodynamic model that best represents your system.
4. Add Unit Operations – Drag and drop equipment from the library.
5. Connect the Flow Sheet – Link the units with process streams.
6. Set Operating Conditions – Specify temperature, pressure, reflux ratio, and other parameters.

4.4 Running the Simulation

Click the **Run**button to initiate the calculation. Monitor the status bar for convergence messages. If the simulation fails to converge:

- Check for missing data or inconsistent units.
- Adjust the initial guess for variables.
- Refine the property method or change the solution algorithm.

4.5 Validating Results

After convergence, review the following:

- Material balances – Ensure mass is conserved.
- Energy balances – Verify energy conservation.
- Unit performance – Compare with design specifications.
- Sensitivity analysis – Assess how changes in input affect outputs.

5. Thermodynamic Models: Choosing the Right One

5.1 Overview of Property Methods

Aspen HYSYS offers a variety of thermodynamic models. The choice depends on the system’s characteristics:

Method	Best For
Peng–Robinson (PR)	Hydrocarbons, natural gas, and moderate pressures.
Soave–Redlich–Kwong (SRK)	Light hydrocarbons and high temperature processes.
Wilson	Mixtures with significant non idealities.
UNIFAC	Polar compounds and complex mixtures.
GERG 2008	Natural gas mixtures with high accuracy.

5.2 Practical Tips

- Start with a simple model (e.g., PR) and refine if necessary.
- Use the Property Method Selection Wizard to guide you.
- Validate with experimental data or literature values.
- Consider the impact on convergence speed and accuracy.
